Prior to attempting these exercises ensure you have read the lecture notes and/or viewed the video, and followed the practical. You may wish to use the Python interpreter in interactive mode to help work out the solutions to some of the questions.

Download and store this document within your own filespace, so the contents can be edited. You will be able to refer to it during the test in Week 6.

Enter your answers directly into the highlighted boxes.

For more information about the module delivery, assessment and feedback please refer to the module within the MyBeckett portal.

Specify two ways in which a Set varies from a List.

Answer:

Sets are immutable and collection of unordered values whereas lists are mutable and collection of ordered values.

Write a Python statement that uses the set() constructor to produce the same Set as the following -

```
languages = { "C++", "Java", "C#", "PHP", "JavaScript" }
```

Answer:

```
languages = {"C++", "Java", "C#", "PHP", "JavaScript"}
new_set = set(languages)
print(new_set)
```

Is a Set mutable or immutable?

Answer:

immutable

Why does a Set not support indexing and slicing type operations?

Answer:

Sets do not support indexing and slicing because they are inherently unordered and have no concept of positions or indices for their elements.

Why is a frozenset () different from a regular set?

Answer:

A frozenset() is different from a regular set because a frozenset supports only the accessor type operations, since it is immutable, whereas a regular set supports both mutators and accessors.

How many elements would exist in the following set?
<pre>names = set("John", "Eric", "Terry", "Michael", "Graham", "Terry")</pre>
Answer:
TypeError: set expected at most 1 argument, got 6
And how many elements would exist in this set?
<pre>vowels = set("aeiou")</pre>
Answer:
5
What is the name given to the following type of expression which can be used to programmatically populate a set?
chars = $\{chr(n) \text{ for n in range}(32, 128)\}$
Answer:
Set comprehension
What operator can be used to calculate the intersection (common elements) between two sets?
Answer:
'&' (ampersand) operator
What operator can be used to calculate the difference between two sets?
Answer:
'-' (minus) operator

What would be the result of each of the following expressions?

```
\{ "x", "y", "z" \} < \{ "z", "u", "t", "y", "w", "x" \}
```

Answer:

True

$$\{ x'', y'', z'' \} < \{ z'', y'', x'' \}$$

Answer:

False

```
\{ "x", "y", "z" \} <= \{ "y", "z", "x" \}
```

Answer:

True

```
\{ "x" \} > \{ "x" \}
```

Answer:

False

$$\{ "x", "y" \} > \{ "x" \}$$

Answer:

True

```
\{ \text{"x", "y"} \} == \{ \text{"y", "x"} \}
```

Answer:

True

Write a Python statement that uses a **method** to perform the equivalent of the following operation -

```
languages = languages | { "Python" }
```

Answer:

languages = languages.union({"Python"})

Do the elements which are placed into a set always remain in the same position?
Answer:
No
Is the following operation a mutator or an accessor ?
languages &= oo_languages
Answer:
mutator
What term is often used to refer to each <i>pair</i> of elements stored within a dictionary ?
Answer:
Key: value pair
Is it possible for a dictionary to have more than one key with the same value?
Answer:
yes
Is it possible for a dictionary to have the same value appear more than once?
Answer:
yes

Α	nsv	ver:

mutable			

Are the **key** values within a dictionary **mutable** or **immutable**?

Answer:

```
immutable
```

How many *elements* exist in the following dictionary?

```
stock = {"apple":10, "banana":15, "orange":11}
```

Answer:

3 key value pairs elements

And, what is the data-type of the keys?

Answer:

The data-type of the keys of dictionary stock is string.

And, what output would be displayed by executing the following statement -

```
print(stock["banana"])
```

Answer:

15

Write a Python statement that uses the dictionary() constructor to produce the same dictionary as the following -

```
lang gen = { "Java":3, "Assembly":2, "Machine Code":1 }
```

Answer:

```
lang_gen = dict({"Java": 3, "Assembly": 2, "Machine Code": 1})
```

Now write a simple expression that tests whether the word "Assembly" is a member of the dictionary.

Answer:
print("Assembly" in lang_gen)
Write some Python code that uses a for statement to iterate over a dictionary called
module_stats and print only its values (i.e. do not output any keys) -
Avanuari
Answer: for value in module_stats.values():
print(value)
Now write another loop which prints the only the keys -
The wind another loop winds printe the city the Reys
Answer:
for key in module_stats.keys(): print(key)
print(key)
Is it possible to construct a dictionary using a comprehension style expression, as
supported by lists and sets?
Answer:
yes
When a Dictionary type value is being passed as an argument to a function, what characters
can be used as a prefix to force the dictionary to be unpacked prior to the call being made?
Annuari
Answer: double-asterisk ('**')
